- Correctly implement the **primitives** of LLM agents, without any assumptions about what LLM or prompts the developer wants to use

- Be **hackable**, but provide reasonable defaults: allow researchers to swap underlying LLMs or edit core logic with minimal hassle

- Be **lightweight** and developer-friendly: enough to get started in under an hour, but powerful enough for a wide range of uses

What properties are desirable in an agent framework in order to effectively build LLM agents that are effective and robust in both research and production?
